CP AND CPT STUDIES WITH KAONS

JULIET LEE-FRANZINI[a]
Laboratori Nazionali di Frascati, Via E. Fermi 40, Frascati, I-00044 Italy

Three European experiments are engaged at present in the study of CP violation in the kaon system. In particular, NA48/1 and KLOE are concerned with the K-short decaying into three pions, while NA48/2 and KLOE study the charged kaon decaying into three pions' Dalitz plot asymmetries. I will discuss the physics involved as well as summarize the anticipated sensitivities which can be reached by the experiments.

1 Introduction

I will precede my discussion of what is expected, from on-going and future experiments on CP violation and CPT tests, with a few historical reminders, to place the present measurements in perspective. The kaons were discovered around 1947, as a surprise, and since then, they have been a cornucopia for particle physics. We owe to them the ideas of "flavor","quark", and "flavor mixing". Parity violation first showed up in the "$\tau - \theta$" puzzle. From semi-leptonic decays we learnt of the $\Delta S = \Delta Q$ rule and obtained the first value of $\sin\theta_{\rm C}$. The kaons' two pion decays taught us the dominance of $\Delta I = 1/2$ transitions, whose explanation is still being labored over by lattice and chiral perturbation physicists. Finally, of course, CP violation, $\not{C}\not{P}$ in the following. Indirect CP violation had been discovered long ago and direct CP violation has only just been definitively established, in the neutral kaon system.

Just for nostalgia, I list some "recent" historical dates: (1) 1964 $\not{C}\not{P}$ in $|\Delta S| = 2$ seen. (2) 1967-1973 $\mathcal{A}_\ell^L \sim \sqrt{2}\Re\epsilon$. (3) 1970-1980 $|V_{us}|$=0.220 ±1.1% experimentally. (4) 2001 Direct $\not{C}\not{P}$ in $|\Delta S| = 1$ established. (5) 2001 $\not{C}\not{P}$ in $|\Delta B| = 2$ seen. (6) 1960-Today $M(K_L) - M(K_S)$, ϵ, $\Re(\epsilon'/\epsilon)$ etc, accuracies are being improved. (7) 1990's $|M(K^0) - M(\bar{K^0})| < 4.5 \times 10^{-10}$ eV.

---

2 Other $\not{C}\not{P}$ Kaon Physics

In the near future, three experiments in Europe, NA48/1[1], NA48/2[2], and KLOE, are set to do the first five measurements listed below. The sixth needs such high intensity kaon beams that given the fiscal stringency at CERN (so that its proposed high-intensity proton driver[3] is not likely to be built), probably can only be realized in the U. S., if KOPIO at BNL is funded. (1) $K_S \to \pi^0\pi^0\pi^0$, BR$\sim 2\times 10^{-9}$: NA48/1, KLOE 2004. (2) Odd pion slopes from K^+-K^-: NA48/2, KLOE 2004. (3) $K^\pm \to \pi^\pm\pi^0\gamma$, NA48/2, KLOE 2004. (4) $\Gamma(K^+ \to \pi^+\pi^+\pi^-) - \Gamma(K^- \to \pi^-\pi^-\pi^+)$: KLOE 2004. (5) $K_S \to \pi^0 e^+ e^-$: NA48/1, KLOE 2004. (6) $K_L \to \pi^0 \nu\bar{\nu}$: BR$\sim 3\times 10^{-11}$, KOPIO 20??. The above list is in order of experimental difficulty and descending branching ratios, BR's. The expected signals are quite predictable theoretically for items 1 and item 6, while the situation is different for items 2, 3 and 4. Item 5 is an ancillary measurement, useful for isolating the direct CP violating component in $K_L \to \pi^0 e^+ e^-$.

2.1 $K_S \to \pi^0\pi^0\pi^0$

Since there has been some confusion in what this BR should be lately, I will write down a couple of lines on its derivation.

Let: $|\,K_S\,\rangle = |\,K_1\,\rangle + \epsilon|\,K_2\,\rangle$; $K_L = |\,K_2\,\rangle + \epsilon|\,K_1\,\rangle$; $\eta_i = \langle i|\,K_L\,\rangle / \langle i|\,K_S\,\rangle$; $\epsilon = (2\eta_{+-} + \eta_{00})/3$. Then:

$$\eta_{000} = \frac{\langle 3\pi^0|\,K_L\,\rangle}{\langle 3\pi^0|\,K_S\,\rangle} = \epsilon + \epsilon'_{000}; \quad |\epsilon'_{000}/\epsilon| \ll 1$$

$$\mathrm{BR}(K_S \to 3\pi^0) = |\eta_{000}|^2 \times \mathrm{BR}(K_L \to 3\pi^0) \times \frac{\Gamma_L}{\Gamma_S} = |\epsilon|^2 \times \mathrm{BR}(K_L \to 3\pi^0) \times \frac{\tau_S}{\tau_L}$$

Putting in the presently known values of ϵ, the $K_L \to 3\pi^0$ branching ratio and the lifetimes of K_S and K_L, the branching ratio for the $\not{C}\not{P}$ decay of K_S to 3 neutral pions is BR$(K_S \to 3\pi^0) = 1.9 \times 10^{-9}$ with an uncertainty of $\sim$1.3%.

The best experimental information to date is from a test run for NA48/1. They have no signal with preliminary values of the uncertainties of:

$$\delta\Re\,\eta_{000} \sim 2.2\times 10^{-2},\ \delta\Im\,\eta_{000} \sim 2.8\times 10^{-2},$$

from which it follows that $\delta\mathrm{BR}(K_S \to 3\pi^0) \sim 4.6 \times 10^{-7}$ or BR $< 0.8 \times 10^{-6}$ at 90% cl.

2.2 $K^\pm \to 3\pi$

Both the partial decay rate and slope parameter, g, asymmetries in three pion charged kaon decays yield information on CP violation. In fact, they offer new means to detect "direct CP violation". Unfortunately, the expected effects are woefully small. For instance, observation of $\Gamma(K^+ \to \pi^+\pi^+\pi^-) \neq \Gamma(K^- \to \pi^-\pi^+\pi^-)$ implies direct CP-violation.

There are four $\not{C}\not{P}$ asymmetries:

$$\mathcal{A}_\Gamma = \frac{\Delta\Gamma}{2\Gamma} = \frac{\Gamma(K^+ \to 3\pi) - \Gamma(K^- \to 3\pi)}{\Gamma(K^+ \to 3\pi) + \Gamma(K^- \to 3\pi)}$$

$$\mathcal{A}_g = \frac{\Delta g}{2g} = \frac{g(K^+ \to 3\pi) - g(K^- \to 3\pi)}{g(K^+ \to 3\pi) + g(K^- \to 3\pi)}$$

for both $\tau^\pm$, *i.e.* $\pi^\pm\pi^+\pi^-$ and $\tau'^\pm$ or $\pi^\pm\pi^0\pi^0$.

The asymmetry arises from the interference of two $\Delta I = 1/2$ amplitudes a and b. There is no $\Delta I = 3/2$ suppression, therefore $|\Im a/\Re a| \sim |\Im b/\Re b| \sim 10^{-4}$. However, to lowest order in chiral perturbation $\arg a = \arg b$. Asymmetries in SM are therefore very small. For example:

$$\mathcal{A}_g = \left(\frac{\Im b}{\Re b} - \frac{\Im a}{\Re a}\right)\sin(\alpha_0 - \beta_0) = \mathcal{O}(10^{-6})$$

where α_0 and β_0 are small rescattering phases, and $\sin(\alpha_0 - \beta_0) \sim 0.1$. From Maiani and Paver[4]:

$$\begin{aligned}
\mathcal{A}_g, \tau &= (-2.3 \pm 0.6) \times 10^{-6} \\
\mathcal{A}_g, \tau' &= (1.3 \pm 0.4) \times 10^{-6} \\
\mathcal{A}_\Gamma, \tau &= (-6 \pm 2) \times 10^{-8} \\
\mathcal{A}_\Gamma, \tau' &= (2.4 \pm 0.8) \times 10^{-8}
\end{aligned}$$

But where things are small, big surprises might hide. D'Ambrosio, Isidori, and Martinelli[5] state that large $\not{C}\not{P}$ effects, A_g of $\mathcal{O}(10^{-4})$, could be triggered by a misalignment of quark and squark mass matrices through the chromomagnetic operator - CMO: *possible only if several conditions conspire in the same direction.* Fine tuning becomes then necessary for explaining the experimental value of $\Re(\epsilon'/\epsilon)$.

3 $K_S \to \pi\ell\nu$

From this reaction one can learn about $\Delta S = \Delta Q$ and TCP violation by measuring (a) the rate $\Gamma(K_S \to \pi\ell\nu)$ and (b) the leptonic asymmetry $\mathcal{A}_\ell^S$.

3.1 $\Delta S = \Delta Q$

There is no $\Delta S = -\Delta Q$ in the SM. We only have $s \to W^- u$, $\bar{s} \to W^+ \bar{u}$. The diagram illustrates a fake $\Delta S = -\Delta Q$ process, if we were just to look at the final lepton sign. At the *su* vertex $\Delta S = \Delta Q$.

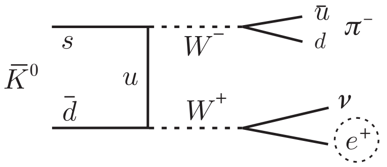

Fig. 1. $\bar{K}^0$ decay to a "wrong" sign lepton.

From fig. 1, the amplitude ratio $x_{\ell 3} = A(\bar{K} \to \ell^+\pi^-\nu)/A(\bar{K} \to \ell^-\pi^+\bar{\nu})$, is $\mathcal{O}(Gm^2) \sim 10^{-6}$, for reasonable values of $m \sim m_K - m_\pi$. Experimentally: $x_{\ell 3} < 10^{-2}$ @ 90% CL, thus its measurement must be improved

3.2 TCP, $\Delta S = \Delta Q$ and leptonic asymmetry

We define the "semileptonic" asymmetry in $K_{S,L-\ell 3}$ decays as $\mathcal{A}_\ell^{S,L} = (N(e^+) - N(e^-)/(N(e^+) + N(e^-))$. From TCP and $\Delta S = \Delta Q$ it follows that $\mathcal{A}_\ell^S = \mathcal{A}_\ell^L$. It is not possible however to disentangle the effects of TCP and $\Delta S = \Delta Q$ within the K_S-K_L system. It is necessary to combine results from K^0 (or $\overline{K}^0$) states, tagged by strong interactions. One needs *eg*, $e^+e^- \to \phi \to K^+K^-$. One $K^\pm$ tags the other. Charge exchange, in any material, gives K^0(or $\overline{K}^0$).
TCP can be violated in mass-matrix and/or decay amplitudes. There are 5 complex parameters for $K \to \pi\ell\nu$: δ, the $\Delta S = \Delta Q$ amplitudes a, b and the $\Delta S = -\Delta Q$ amplitudes c, d satisfying:

$$2\delta = \epsilon_S - \epsilon_L$$

$$\begin{array}{ll}
\Re(a,c) & TCP\text{–even} \\
\Im(a,c) & TCP\text{–even} \\
\Re(b,d) & TCP\text{–odd} \\
\Im(b,d) & TCP\text{–odd}
\end{array}$$

If $c = d = 0$, then $\mathcal{A}_\ell^S - \mathcal{A}_\ell^L = 4\Re\delta$. A limit from the above improves the determination of $\left(M(K^0) - M(\bar{K}^0)\right)/M$. Do note that one needs many $\times 10^{10}$ K's, therefore tens of fb^{-1} at a ϕ–factory, not easy to come by.

4 CP, Unitarity and Triangles

The proverbial price of $\not{C}\not{P}$: $J = A^2\lambda^6\eta$=$(2.7 \pm 1.1) \times 10^{-5}$, is poorly known. J is also (2×)area of all unitary triangles. We must check the closing of all triangles and compare their areas. There are still many measurements needed for B's, and two more for K's, ignoring D's for the moment. We use in the following Wolfenstein's notation. The mixing martix parameters are λ=0.22 to $\sim$1%, $A$$\sim$0.84±0.09, $|\rho - i\eta| \sim 0.3 \pm 0.15$.

4.1 The K Triangle

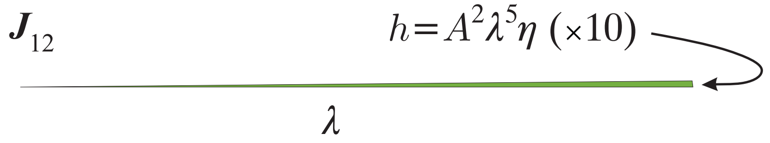

Fig. 2. The unitary triangle for kaons.

The error on J_{12} is given by

$$\frac{\delta J_{12}}{J_{12}} = 6\% \oplus \frac{\delta\eta}{\eta}$$

The decay rate for $K_L \to \pi^0\nu\bar{\nu}$, measures directly η: $\Gamma(K_L \to \pi^0\nu\bar{\nu}) \propto \eta^2$ and $J_{12} = \lambda(1 - \lambda^2/2)\Im(V_{td}V_{ts}^*) \cong 5.6[\text{BR}(K_L \to \pi^0\nu\bar{\nu})]^{1/2}$. Thus 100 events determine $\delta\eta/\eta$ to 5% and J_{12} to $\sim$8%. More measurements, indicated in fig. 3, do over-constrain the $\rho - \eta$ determination.

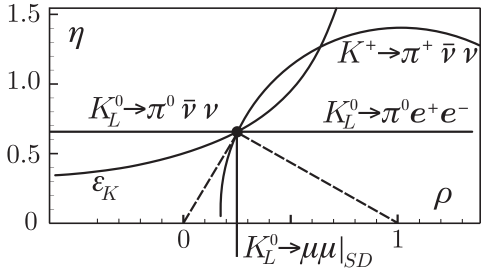

Fig. 3. Constraints for kaons.

So far there are only two $K^+ \to \pi^+\nu\bar{\nu}$ events, in agreement with BR$\sim$$1.5 \times 10^{-10}$ and only hopes of observing $K_L \to \pi^0\nu\bar{\nu}$.

4.2 Unitarity

The most stringent proof of unitarity of the mixing matrix so far is the extended GIM cancellation in $M(K_L) - M(K_S)$ and $K^0 \to \mu\mu$. Additional testing should not be limited to the closing of a triangle, but of all triangles, and verifying the equality of the areas of all triangles.

5 DAΦNE and KLOE

The descriptions of NA48/1 and NA48/2 were given in glorious detail in the talks by Richard Batley and Gianmaria Collazuol respectively and appear in these proceedings. However, DAΦNE the particle accelerator and KLOE, its main detector, are part of my talk, hence their goals are included here. The relevant DAΦNE parameters are given in table 1.

Table 1. DAΦNE parameters.

Parameter	Design	2001	2004
Bunches	120	45	120
Current (A)	5	1.2	
Ł (μb^{-1} s^{-1})	5×10^{32}	5×10^{31}	5×10^{33}
Beam τ (m)	$\gg$100	<20	
$\int$Łdt pb^{-1}	5000	~190	50,000

5.1 The uniqueness of a ϕ–factory

In the reaction $e^+e^-\rightarrow\phi\rightarrow$neutral kaons, the initial state is

$$|\,i\,\rangle=\frac{|\,K^0,\mathbf{p}\,\rangle|\,\overline{K}^0,-\mathbf{p}\,\rangle-|\,\overline{K}^0,\mathbf{p}\,\rangle|\,K^0,-\mathbf{p}\,\rangle}{\sqrt{2}}$$

Defining $|\,K_S\,\rangle\equiv p'|\,K^0\,\rangle+q'|\,\overline{K}^0\,\rangle$ and $|\,K_L\,\rangle\equiv p|\,K^0\,\rangle-q|\,\overline{K}^0\,\rangle$ with $|p'|^2+|q'|^2=1$ and $|p|^2+|q|^2=1$ we can also write

$$|\,i\,\rangle=\frac{|\,K_S,\mathbf{p}\,\rangle|\,K_L,-\mathbf{p}\,\rangle-|\,K_L,\mathbf{p}\,\rangle|\,K_S,-\mathbf{p}\,\rangle}{\sqrt{2(qp'+q'p)}}$$

Therefore at DAΦNE one has pure K_L, K_S, K^0, $\overline{K}^0$ beams. From unitarity and $\sigma(\gamma\gamma\rightarrow K^0\overline{K}^0, J^P=0^+)$ we find $(e^+e^-\rightarrow K_SK_S$ or $K_LK_L)/(e^+e^-\rightarrow\phi\rightarrow K_SK_L)\sim$ few $\times\,10^{-10}$

This gives us a unique opportunity to study: (a) K_S BR's to high accuracy and (b) K_S rare decays: K_S semileptonic decays, $K_S\rightarrow\pi^0\pi^0\pi^0$, $K_S\rightarrow\pi^0\nu\bar{\nu}$, in addition to CP and CPT, the original mission of KLOE. Furthermore, KLOE can also study the neutral kaon system by "interferometry".

6 KLOE's experimental program

Some topics of interest in KLOE's future are: (1) measure kaon CP violating parameters, also by interference; (2) measure V_{us}, (3) find $K_S\rightarrow\pi^0\pi^0\pi^0$; (4) study $K_S\rightarrow\pi\ell\nu$; (5) verify $\Delta S=\Delta Q$; (6) keep an eye on TCP, and (7) hopefully peek beyond the SM.

6.1 Kaon CP violating parameters by kaon interferometry

Interference allows the measurements of magnitude and phases of the kaon decay amplitudes without identifying long and short-lived kaons. Consider the configuration illustrated

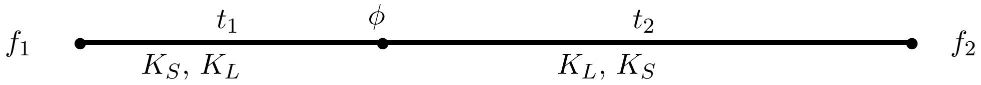

Fig. 4. The decay $\phi\rightarrow KK\rightarrow f_1, f_2$.

The decay intensity is given by:

$$\begin{array}{c}I(f_1,f_2,t_1,t_2)=|\langle\,f_1|\,K_S\,\rangle|^2|\langle\,f_2|\,K_S\,\rangle|^2e^{-\Gamma_S\,t/2}\times\\ \left[|\eta_1|^2e^{\Gamma_S\Delta t/2}+|\eta_2|^2e^{-\Gamma_S\Delta t/2}-2|\eta_1||\eta_2|\cos(\Delta m\,t+\phi_1-\phi_2)\right]\end{array}.$$

Integrating over t_1 and t_2, for $\Delta t=t_1-t_2$ constant we find:

$$\begin{array}{c}I(f_1,\ f_2;\ \Delta t)=\dfrac{1}{2\Gamma}|\langle f_1|\,K_S\,\rangle\langle f_2|\,K_S\,\rangle|^2\times[|\eta_1|^2e^{-\Gamma_L\Delta t}+\\ |\eta_2|^2e^{-\Gamma_S\Delta t}-2|\eta_1||\eta_2|e^{-\Gamma\Delta t/2}\cos(\Delta m\Delta t+\phi_1-\phi_2)]\end{array}$$

We can thus measure ΔM, Γ, η_i phases. $(\eta_i=A(K_L\rightarrow i)/A(K_S\rightarrow i),\ \arg(\eta)=\phi)$.

6.2 Interference examples

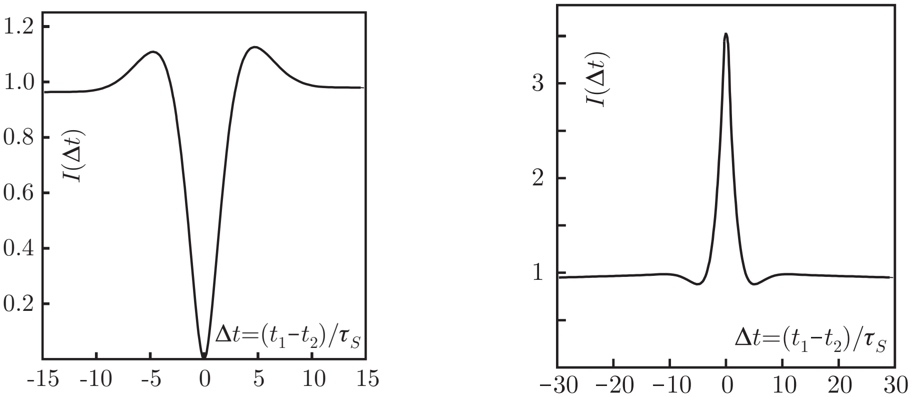

Fig. 5. Interference patterns. Left $f_{1,2}$=$\pi^+\pi^-$,$\pi^0\pi^0$, sensitive to $\Re(\epsilon'/\epsilon)$ and $\Im(\epsilon'/\epsilon)$. Right $f_{1,2} = \ell^-, \ell^+$ yielding $\Re$ and $\Im$ of $A_{\ell^\pm}$

6.3 $\Gamma(K_S \to \pi^+\pi^-)/\Gamma(K_S \to \pi^0\pi^0)$, KLOE 2001

After all these years, chiral "perturbationists" are still trying to reach some accuracy in postdicting the $\Delta I = 1/2$ rule. Its understanding would allow a more reliable calculation of $\Re(\epsilon'/\epsilon)$. Experimentally KLOE will measure the BR's for K_S decays (and K_L) into various channels with high accuracy. The ratio $R = \Gamma(K_S \to \pi^+\pi^-)/\Gamma(K_S \to \pi^0\pi^0)$ is not well known, only to a couple of %, even though the double ratio $(K_L \to +- \; K_L \to 00)/(K_S \to +- \; /K_S \to 00)$ is known to ∼0.1% .

KLOE would like to reach 0.1% on the former. Corrections are background sensitive. Luckily, K_L interacting in the KLOE calorimeter gives an ideal K_S tag, almost independent of K_S decay mode. For our first measurement of this ratio we obtain: $R = 2.239 \pm 0.003(\text{stat.}) \pm 0.015(\text{syst.})$[6]. Not only is this determination far more accurate than Particle Data Group' compilation, it is very important to note that KLOE includes all $K_S \to \pi^+\pi^-\gamma$, whereas the other previous experiments include unknown fractions, making comparison with theoretical calculations ambiguous. The above measurement is based on only 16 pb^{-1}. KLOE in 2002 has about 30 times that amount of data to improve the accuracy of the measurement.

6.4 $K_S \to \pi e \nu$, KLOE 2001

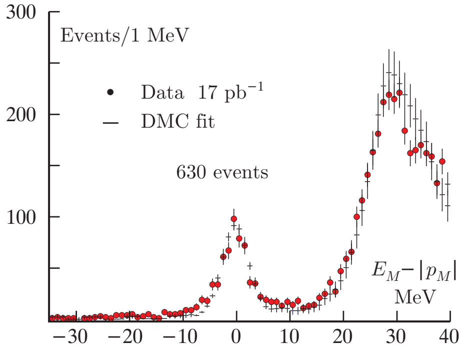

Fig. 6. The signal for $K_S \to e^\pm \pi^\mp \nu$ in KLOE.

In the KLOE measurement of this process in 2001, we use only non spiraling tracks, time-of-flight, TOF, for electron identification and compare the missing energy, E_{miss}, with the missing momentum, $|p_{miss}|$, thus achieve an almost completely rejection of $\pi^+\pi^-$ backgrounds, as seen fig. 6. We find: BR=$(6.91 \pm 0.37) \times 10^{-4}$ [7]. By end of 2002, KLOE will improve this measurement with 30 times more statistics, and will have the first measurement of $\mathcal{A}_\ell^S$.

7 Expectations from the coming experiments

7.1 $\Re(\epsilon'/\epsilon)$ *via the double ratio method*

A review of the status of direct CP violation experiments has been given by B. Peyaud at this Rencontre, all references for NA48 and KTEV are in his article in this proceedings. Fig. 7 shows the luminosity that KLOE needs to reach various accuracies on $\Re(\epsilon'/\epsilon)$ by measuring the double ratio. KLOE's measurement will be performed at a ϕ–factory, with totally different systematics from the fixed target experiments. Furthermore, it will be charming, if nothing else, to see the interference patterns done with high accuracy.

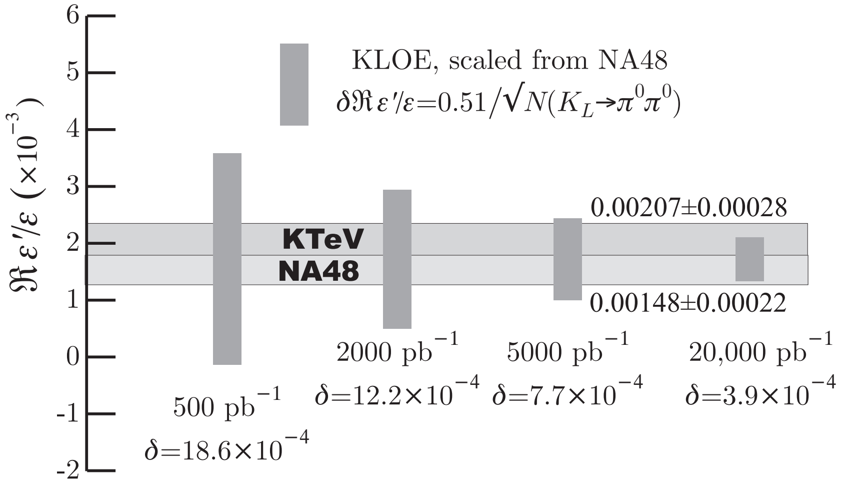

Fig. 7. KLOE expectations vs NA48 and KTeV.

7.2 $K^\pm$ *Decays*

Details and expectations of NA48/2 are given in Gianmaria Collazuol's paper. Table 2, is a summary of results expected from NA48/2 and KLOE (Acc. stands for acceptance).

Table 2. $K^\pm$ decays.

Mode	BR	Acc.	Events	Acc.	Events	Note
		KLOE		NA48/2		
$K^\pm \to \pi^+\pi^-\pi^\pm$	0.056	0.03	1.26×10^8		2×10^9	(1)
$K^\pm \to \pi^0\pi^0\pi^\pm$	0.017	0.09	1.22×10^8		1.2×10^8	(2)
$K^\pm \to \pi^\pm\pi^0\gamma$	2.8×10^{-4}	0.1	2×10^6	0.1	1×10^6	(3)
$K^\pm \to \pi^\pm\gamma\gamma$	5×10^{-7}	0.15	3750			

(1). KLOE: δA_g=4×10^{-4}, δA_Γ=10^{-4}. NA48/2: δA_g=2×10^{-4}.
(2). KLOE: δA_g=2×10^{-4}, δA_Γ=10^{-4}. NA48/2: δA_g=3.5×10^{-4}.
(3). KLOE: δA_Γ=10^{-3}. NA48/2 δA_Γ=10^{-2}.

7.3 K_S *and* K_L *decays*

The experimental setups and expectations of NA48/1 are described in detail by Richard Batley in these proceedings. In table 3, I only summarize their anticipated results in comparison to those expected from KLOE (Acc. stands for acceptance).

Table 3. K_S and K_L decays.

Mode	BR	Acc.	Events	Acc.	Events	Note
		KLOE		NA48/1		
$K_S \to \pi^+\pi^-$	0.67	0.15	5×10^9			
$K_S \to \pi^0\pi^0$	0.31	0.15	2.5×10^9			
$K_S \to \pi e \nu$	7.4×10^{-4}	0.05	2×10^6			
$K_S \to \pi^0 e^+ e^-$	5.2×10^{-9}	0.05	13	0.05	7	Ind $\not{C}\not{P}$
$K_S \to 3\pi^0$	2×10^{-9}	0.17	16	0.05	4	η_{000}
$K_S \to \pi^0\gamma\gamma$	4×10^{-8}	0.15	300	0.1	114	
$K_S \to \pi^+\pi^-\gamma$	1.8×10^{-3}	0.15	1.35×10^7			
$K_S \to \pi^+\pi^-\pi^0$	3.2×10^{-7}	0.17	2500			
$K_L \to \pi^+\pi^-\pi^0$	0.12	0.16	1×10^9			
$K_L \to \pi^+\pi^-$	0.002	0.11	1.1×10^7			
$K_L \to \pi^0\pi^0$	0.001	0.1	4×10^6			
$K_L \to \pi^+\pi^-\gamma$	4.6×10^{-5}	0.16	3.7×10^5			

8 Conclusions

NA48/1 and NA48/2 will (presumably) have results by 2004. KLOE will begin taking data in 2004. Thereafter one needs more intense kaon sources to attack the golden processes $K_L \to \pi^0 \nu \bar{\nu}$, $\to \pi^0 e^+ e^-$. After all these experiments are done there might still be some missing points: (a) will the origin of $\not{C}\not{P}$ still be unknown? (b) $\Re(\epsilon'/\epsilon) \neq 0$ rules out the superweak theory, but will the connection between CKM and $\Re(\epsilon'/\epsilon)$ still evades us? We have studied $\not{C}\not{P}$ for 39 years, we still have quite a few more to go.

9 Acknowledgements

I want to thank J. Tran Thanh Van and Lydia Iconomidou-Fayard for organizing this most enjoyable and lively "XIVth Rencontres DE BLOIS : *Matter-Antimatter Asymmetry*" where so many of our colleagues could present and exchange ideas in a most convivial atmosphere.
